Agenda

- Address Operator
- Definition of a pointer
- · Syntax of a pointer
- Creating pointer variables and accessing those
- Use of Dereference Operator
- Pointer to Pointer
- Pointer Arithmetic (Increment/Decrement)

What is a file?

- Unit of stored data that is identifiable by a unique name and stored in a filesystem.
- It can contain various types of information, such as text, images, videos, executable code, or any other form of data.
- ► Files can be of various types, but we will work with text files.

File Handling

A mechanism to store the output of a program in a file, get the data in a program from a file.

Why Filing, when we have arrays/variables to store data:

Files help store these data permanently on a storage device.

Stream:

Stream means flow of data, data can flow from console to the execution program, and from execution program to the console.

Fstream

- Header file, which gives access to file handling methods in C++
- Three classes of fstream:
 - ofstream
 - ifstream
 - fstream

fstream library

ofstream:

Helps to write data to the file, also known as output stream

ifsream:

Helps to read data from the file, also called input stream

fstream:

Combination of ifstream and ofstream, provides capability of reading and writing a file

File operations in C++

1

open() – This is used to open/create a file.

2

read() – This is used to read the data from the file.

3

write() – This is used to write new data to file.

4

close() – This is used to close the file.

Opening a file

To read or enter data to a file, we need to open it first.

Syntax:

```
1 | open( FileName , Mode );
```

Here:

FileName – It denotes the name of file which has to be opened.

Mode – There different mode to open a file and it explained in this article.

Mode	Description
iso::in	File opened in reading mode
iso::out	File opened in write mode
iso::app	File opened in append mode

Modes for a file

THIS IS IOS NOT ISO

Code for opening a file

```
int main(){
fstream File;
File.open("A.txt",ios::in);

if(!File){
    cout<<"Error";
}
else{
    cout<<"Found the file";
    File.close();
}
return 0;
}</pre>
```

Explanation of the code

- 1. We have a fstream library, which is responsible for handling files.
- Creating an object of the fstream class and named it as 'File'.
- 3. On the above-created object, we have to apply the open() function to create a new file, and the mode is set to 'out' which will allow us to write into the file.
- 4. We use the 'if' statement to check for the file creation.
- 5. Prints the message to console if the file doesn't exist.
- 6. Prints the message to console if the file exists/created.
- 7. We use the close() function on the object to close the file.

Code for creating a file

```
fstream File;
File.open("B.txt",ios::out);
```

Writing to a file

- We will use stream insertion operator (<<) along with the text enclosed within the double-quotes.
- With open() function, we will create a new file named 'FileName' and then we will set the mode to 'ios::out' as we have to write the data to file

Code for writing the data

```
#include<iostream>
#include<fstream>
using namespace std;
int main(){

    ofstream MyFile("FileName.txt");
    MyFile<<"Hello Filing"<<endl<<"we are doing good";

    MyFile.close();
    return 0;
}</pre>
```

Reading data from a file

For reading the data from a file, we will have to assure that file must exist

▶ We will open the file in ios:in mode

```
int main(){

ifstream ReadFile("C.txt",ios::in);
string text="";
while(getline(ReadFile,text)){
    cout<<text;
}

return 0;
}</pre>
```

Code for Reading the data

Writing an array to the file

Reading from file to array

Tasks

- Write code for writing to the file named MyFile.txt, with the help of ofstream.
- Write following message: "There are no secrets to success"

Tasks

Create a function which takes an array of employee names as its parameter

The function stores each element of the array on a new line of the file named Emp_names.txt
